

STEPS TO MOUNT A DISK ON UBUNTU

1. Check for the disk by running: **lsblk**
2. Check to see if the disk already has a file system (was used already) by using the command: **sudo file -s /dev/nvme1n1**, if the result is just data, means we need to format it (all data will be cleared) using the command **sudo mkfs.ext4 /dev/nvme1n1** else we leave it like that and use it.
3. Mount the disk so we can store data inside it using the command: **sudo mkdir /data** and **sudo mount /dev/nvme1n1 /data**
4. Use this command to unmount a volume: **sudo umount /data**
5. Now to persist the mounts after reboot, follow the following steps:
 - ◆ Find the UUID of the disk using the command: **sudo blkid /dev/nvme1n1**
 - ◆ Edit the *etc/fstab* file and add the line : **UUID=1234-5678 /data ext4 defaults,nofail 0 2**
 - ◆ Check if the mount was ok and no errors exists using the command: **sudo mount -a**
